ATMELE® is introducing a new 8 bit AVR® family with the ATmega32M1. This family embeds an innovative PSC dedicated to motor control applications and led lighting applications.

Note: This PSC is different that the PSC used in the AT90PWMx family dedicated for lighting. As it is primarily dedicated for motor control and to simplify its use, it is a merge of the three AT90PWMx family PSC. The AVR434 ‘PSC cookbook’ is specially dedicated for the AT90PWMx family PSC and is not applicable for the ATmega32M1 family PSC.

2. Introduction

This application note is an introduction to the use of the Power Stage Controller (PSC) available in ATmega32M1 family. The object of this document is to give a general overview of the PSC, show its various modes of operation and explain how to configure them. The code examples will make this clearer and can be used as guideline for other applications. The examples are developed and tested on ATmega32M1.

PSC description and additional information can be found in the data sheet and in application notes where the PSC is used.

This application note describes waveforms which can be generated by the PSC and how to program it. It also introduces fault modes and output enable management.

All source files are available on the Atmel website. They are written on GCC compiler, nevertheless they can easily modified to compile on other compilers.

3. General Description

The Power Stage Controller is a special timer with 3 modules dedicated to drive the power stage of an equipment or a board. The PSC is logical level compatible and is able to drive a bridge of power transistors.

The PSC can drive different kind of bridges (DC, Brushless DC, AC motors …)
Each of the 3 PSC modules can be seen as a PWM generator with two complementary outputs. To provide a self running PSC mode without the need of embedded software action, the PSC has 3 inputs which can stop the waveform generation. For example, in a current sensing mode, the current can be monitored by a comparator which can stop the PSC waveform when a maximum current is reached.

The PSC can be clocked by a fast clock like the output of a 64 MHz PLL. So it can generate high speed PWM with a high resolution. It can also be clocked by slower clocks such as PLL intermediate output or by CPU clock (CLKio). Moreover it includes a prescaler to generate signals with very low frequency.

4. PSC Applications

The PSC is intended to drive applications with a power stage:
- Motor Control (Waveform Generation and Speed/Torque regulation)
- Led Lighting Control (Current Regulation)

Figure 4-1. Led boost control example

Figure 4-2. Motor control example

Note: Motor can be BLDC or asynchronous motor
5. PSC Modes

5.1 Prerequisite

We recommend reading the following chapters of the ATmega32M1 datasheet:

- Overview
- PSC Description
- Functional Description

5.2 Why Different Modes

The PSC provides 2 modes of operation:

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 ramp mode</td>
<td>This mode is used to generate overlapped waveform. The major risk of this</td>
</tr>
<tr>
<td></td>
<td>mode is when driving a half bridge to have cross-conduction.</td>
</tr>
<tr>
<td>centered mode</td>
<td>The PSC output waveforms are symmetrical and centered. This mode is</td>
</tr>
<tr>
<td></td>
<td>useful for space vector pwm methods to generate sinusoidal waveforms.</td>
</tr>
<tr>
<td></td>
<td>(Overlapped waveforms are possible)</td>
</tr>
</tbody>
</table>

5.3 Running Modes Examples

All examples are written in C and embedded in a AVR Studio GCC project.

These examples are given to quickly start the generation of waveforms and to evaluate the two running modes.

The name of the AVR projects are OneRampMode.aps and CenteredMode.aps.

Thanks to PSC_MODE definition, we can select the running mode.
5.3.1 Mode: one ramp

The One Ramp mode can also be seen as an edge aligned mode.

To select the 1 ramp mode use the following syntax:

```c
#define PSC_MODE PSC_MODE_ONE_RAMP
```

In the following example, CLOCK PSC = CLK PLL = 64 Mhz

**Figure 5-1.** One Ramp Mode

</tbody>
</table>
6. PSC Inputs

6.1 Prerequisite

We recommend reading the following chapters of the ATmega32M1 datasheet:

- Overview
- PSC Description
- PSC Inputs

6.2 Description

The PSC has 3 identical inputs which can be programmed to quickly react on the PSC outputs. The outputs can be de-activated definitively (fault mode) or only during the active state of the selected input. The PSC inputs have a digital filter which can be bypassed to get a shorter reaction time.
The following examples are given to quickly start the use of PSC inputs and to evaluate the input modes. It is done in one ramp mode. Thanks to PSC_MODE definition, they can easily be modified to test inputs in centered mode.

These examples can be used on STK500/STK524 boards.

The name of the AVR project is test_halt.aps.

The PSCIN0 signal is generated by an AGILENT 33250A Function Waveform Generator synchronized on the PSCOUT1B output.

**Synchronous mode versus asynchronous modes of inputs:**

All the following examples are given in synchronous mode (PSC_SYNCHRONOUS_OUTPUT_CONTROL definition), the system clock running is necessary to propagate the PSC input to the PSC output. The user can easily test the direct propagation of the PSC input by using the PSCASYNCHRONOUS_OUTPUT_CONTROL definition in the source files of the examples.

### 6.2.1 Input Mode 1: De-activate module 0 Output A

Comment the #define PSC_TEST_HALT in the source file to get the following waveforms.

Thanks to PSC_USE_HIGH_LEVEL, the PSCIN0 input acts on PSCOUT0A when it is in a high level.
6.2.2 Input Mode 7: Halt PSC and Wait for Software Action

PSCIN0 input can easily be activated by connected PD1 to SW0 switch on STK500 board.

When PSC is in fault state, the software will reset it when PE2 equals 0. So PE2 can be con-
nected to SW1 to restart the PSC.

Thanks to PSC_USE_LOW_LEVEL, the PSCIN0 input acts on PSCOUT0A when it is in a low
level. The restart of the PSC is not possible while PSCIN0 remains active (low level).

Un-comment the #define PSC_TEST_HALT in the source file.

The PSCIN0 configuration uses PSC_INPUT_HALT_PSC when it is involved.
6.2.3 Use of the filter on the PSC inputs

In this example, PSC operates with the 64MHz output of the PLL.

Comment the #define PSC_TEST_HALT in the source file to get the following waveforms.

Un-comment the #define TEST_FILTER

Table 6-1. Settings for Figure 6-4. and Figure 6-5.

<table>
<thead>
<tr>
<th>PSC SFR</th>

<td>0.16µS</td>
</tr>
</tbody>
</table>

6.2.3.1 Filter Propagation Delay

On Figure 6-4. the input filter is enable, the propagation delay equals 92.5nS.

On Figure 6-5. the input filter is disabled, the propagation delay equals 30nS.

The filter delay is 4*Clock cycles, which corresponds to 62.5nS.
Figure 6-4. PSC0IN0 configured to act on PSCOUT0A (filter enabled)

Figure 6-5. PSC0IN0 configured to act on PSCOUT0A (filter disabled)
6.2.3.2 Filter Performance

On Figure 6-6, the input filter is disabled, the 50nS spike on PSCIN0 is propagated on PSCOUT0A.

On Figure 6-7, the input filter is enabled, the 50nS spike on PSCIN0 is not propagated on PSCOUT0A.

Figure 6-6. PSC0IN0 Configured to act on PSCOUT0A (filter disabled)

Figure 6-7. PSC0IN0 Configured to act on PSCOUT0A (filter enabled)
6.2.4 Use of the Comparator (ACMP0) as PSC input

This example demonstrates the use of comparator 0 as PSC input.

The name of the AVR project is Comparator.aps.

The comparator 0 is used as PSC input thanks to Psc_config_input0(..) functions.

Comparator 0 negative input is connected to a 0.9V DC source.

Comparator 0 positive input is connected to the output of an AGILENT 33250A Waveform Generator. The Waveform Generator generates a saw signal from 0 to 2.6V.

We can see that each time the positive input is below the negative input the outputs of the PSC are de-activated.

Figure 6-8. PSC Outputs versus Comparator 0 inputs

6.3 Output Modulation with POC register

This example demonstrates the use of PSC Output Configuration (POC) register to validate or not validate the PSC outputs. This register is useful to drive BLDC motors. It can select the good outputs according to the Hall Sensor values or according to the Back-Emf detection.

The example can be used on STK500/STK524 boards.

The name of the AVR project is OutputEnable.aps.

The user can connect the PSC outputs to the STK500 LED inputs and see a kind of LED chaser where the light intensity of each LED is adjusted by the duty cycle of the corresponding output.
7. PSC Interrupts

The PSC can generate interrupts when a significant event occurs on PSC inputs or at the end of the PSC cycle. This example demonstrates the use of the interrupt at the end of PSC cycle.

The name of the AVR project is Test_Interrupt.aps.

The PSC end of cycle interrupt is enabled and the interrupt routine makes toggle the PD2 pin. The PSC uses the centered mode and the end of cycle is located in the middle of the waveforms.
Figure 7-1. PSC interrupt toggles PD2 pin.
